At what absolute temperature do the Celsius and Fahrenheit temperature scales give the same numerical value? What is the value?

Solution:

Write a function for converting Kelvins into deg C. Then write a second function converting Kelvins into deg F. Plot the two functions with Kelvins as the independent variable. The plot shows the intersection. Setting the two functions equal to each other and solving for the intersection gives -40 deg C or deg F at 233.15 K.

```
In[16]:= (*Calculate deg C and F from Kelvins *)
       (*Variable x is a dummy variable representing Kelvins*)
      c[x_] = x - 273.15;
      f[x_{-}] = (x - 273.15) * \frac{9}{5} + 32;
ln[19]:= Plot[{c[x], f[x]}, {x, 0, 400}]
       300
       200
        100
                                                     300
Out[19]= -100
      -200
       -300
       -400
ln[20]:= Solve[c[x] == f[x]]
Out[20]= \{ \{ x \rightarrow 233.15 \} \}
ln[21]:= c[233.15]
Out[21]= -40.
ln[22] = f[233.15]
Out[22]= -40.
       (*ans: -40 deg C or or -40 deg F at 233.15 K //ANS*)
```

Pressures up to 3,000 bar are measured with a dead-weight gauge. The piston diameter is 4 mm. What is the approximate mass in kg of the weights required?

Solution:

Calculate the area of the piston.

$$\frac{\pi}{4} \left(4. \text{ mm} * \frac{1 \text{ m}}{1000 \text{ mm}} \right)^2$$
0.000 012 566 370 61 m²

Calculate the force from the pressure and the area, knowing that pressure is force per unit area.

3000 bar
$$\frac{\frac{10^5 \text{ N}}{\text{m}^2}}{\text{bar}} * .0000125664 \text{ m}^2$$

3769.92 N

Equate force to mass*g and solve for mass. (We retain units for illustrative purposes only. They can be dropped in this case for a quick calculation.)

$$ln[*]:= eq1 = 3769.92 \text{ N} * \frac{\frac{1 \text{ kg*m}}{s^2}}{1 \text{ N}} = mass * \frac{9.80665 \text{ m}}{s^2}$$

$$Out[*]= \frac{3769.92 \text{ kg m}}{s^2} = \frac{9.80665 \text{ m mass}}{s^2}$$

$$\textit{Out[*]=} \hspace{0.1in} \{\hspace{0.1in} \{\hspace{0.1in} \texttt{mass} \rightarrow \texttt{384.4248546} \hspace{0.1in} kg\hspace{0.1in} \}\hspace{0.1in} \}$$

Therefore, the mass is 384.425 kg //ANS.

It is a good idea to check the answer. This can be done quickly by converting the mass back to a force (in Newtons) and then into a pressure (in Pa) and then converting to pressure in bar.

$$\frac{384 * 9.8}{\pi * .004^2 / 4} / 10^5$$

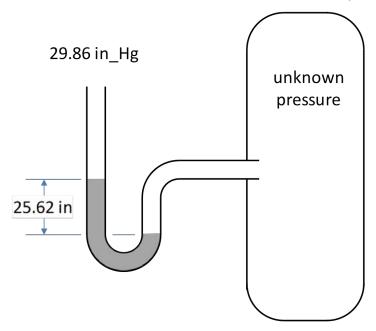

2994.659409

Note that this is about 3,000 bar, as expected.

The reading on a mercury manometer at 70 degF (open to the atmosphere at one end) is 25.62 inches. The local acceleration of gravity is 32.243 $\frac{ft}{s^2}$. Atmospheric pressure is 29.86 inches of mercury (in_Hg). What is the absolute pressure in psia being measured? The density of mercury at 70 degF is 13.543 $\frac{gm}{cm^3}$.

Solution:

A sketch of the manometer is shown below. The sketch shows how the different pressures and mercury height are related.

The absolute pressure in the vessel is the sum of the manometer pressure and the atmospheric pressure.

The manometer pressure is given by ρ gh, where h is the difference in height between the two mercury levels. English units require the conversion factor g_c , so the pressure difference is $\frac{1}{a_c}\rho$ gh. Also, density must be in English units:

$$\frac{\left(\frac{\textbf{13.543 gm}}{\text{cm}^3}\right) \star \left(\frac{\textbf{2.20462 lb}_{\text{m}}}{\textbf{1000 gm}}\right) \star \left(\frac{\textbf{10}^6 \text{ cm}^3}{\textbf{35.3147 ft}^3}\right)}{\textbf{845.460067904 lb}_{\text{m}}}$$

To get absolute pressure, add the guage pressure to the atmospheric pressure (25.62in+29.86in), then apply the manometer equation:

$$\log_{\text{obs}} = \frac{\left(\left(\frac{845.46\,\text{lb}_{\text{m}}}{\text{ft}^3}\right) \star \left(\frac{32.243\,\text{ft}}{\text{s}^2}\right) \star \left(25.62\,\text{in} + 29.86\,\text{in}\right) \star \left(\frac{1\,\text{ft}}{12\,\text{in}}\right)\right)}{\left(\frac{\frac{32.1740\,\text{ft} + 1\text{b}_{\text{m}}}{\text{s}^2}}{1\,1\text{b}_{\text{f}}}\right)} \star \left(\frac{1\,\text{ft}}{12\,\text{in}}\right)^2$$

$$Out[\text{obs}] = \frac{27.2029601512\,\text{lb}_{\text{f}}}{\text{in}^2}$$

The absolute pressure in the vessel is 27.203 psia //ANS.

Alternate Solution 1

A simple solution comes from using the conversion factors in your thermal-fluids text book:.

$$_{\text{In[3]:=}}$$
 (25.62 + 29.86) in_Hg * $\frac{\text{1 atm}}{\text{29.92 in_Hg}}$ * $\frac{\text{14.696 in_Hg}}{\text{atm}}$

Out[3]= 27.2504705882 in_Hg

Alternate Solution 2

Another simple solution comes from using the conversion factors in your CH365 text book (App A, p. 662). However, additional required information is that 1 torr = 1 mm Hg:

$$_{\text{In}[4]:=}$$
 (29.86 + 25.62) in_Hg * $\frac{\text{1000 mm_Hg}}{\text{39.3701 in_Hg}}$ * $\frac{\text{14.5038 psi}}{\text{750.063 torr}}$ * $\frac{\text{1 torr}}{\text{1 mm_Hg}}$

Out[4]= 27.2492149229 psi

Liquids that boil at relatively low temperatures are often stored as liquids under their vapor pressures, which at ambient temperature can be quite large. Thus, n-butane stored as a liquid/vapor system is at a pressure of 2.581 bar for a temperature of 300 K. Large-scale storage ($> 50 \, m^3$) of this kind is sometimes done in spherical tanks. Suggest two reasons why.

Solution:

Reason 1:

For a given volume, the surface area to volume ratio is minimized in a sphere. See examples of area and volume calculations at the end of this document. What does this mean? For a unit volume, the surface area for a sphere is lower than for other shapes. Since heat transfer is proportional to surface area, the same volume of fluid experiences less heat transfer when contained inside a sphere as opposed to a cube or rectangle. Less heat flux means less evaporation, which means the losses should be lower. Engineers have to weigh the costs and benefits of using a more expensive spherical vessel lower fluid losses versus versus less expensive vessels with slightly higher fluid losses.

Reason 2:

A sphere is inherently a very strong structure. The reason for this is the symmetrical and even distribution of stresses on the sphere's surfaces. Generally, this means that there are fewer weak points than in cylindrical vessels. Of course, this reasoning is true only for a "theoretical" sphere. In an actual spherical vessel, there will be imperfections and stress points at the welds between the plates used to fabricate the vessel, but all things being equal, the spherical vessel should be somewhat stronger.

Area per volume examples:

The following are examples of area per volume calculations for a sphere, a cube, three different cylinders, one with h/D=1, one with h/D=2 (tall and narrow), and the other with h/D=1/2 (short and wide), and a triangular pyramid with b=h. We assume the same volume of 50 m^3 for all shapes.

```

The first accurate measurements of the properties of high-pressure gases were made by E.H. Amagat in France between 1869 and 1893. Before developing the dead-weight gauge, he worked in a mine shaft, and used a mercury manometer for measurements of pressure to more than 400 bar. Estimate the height of the manometer required.

Solution:

Since this is an estimate, we do not need highly precise constants. We can assume a density of mercury of about 13.5 $\frac{gm}{cm^3}$, which corresponds to a temperature near 25 degC. The acceleration of gravity is about 9.8 $\frac{m}{s^2}$.

(*Convert the pressure to base units. *)

400. bar *
$$\frac{\frac{100\,000\,kg}{m\,s^2}}{1\,bar}$$

$$\frac{4.\times 10^7\,kg}{m\,s^2}$$
(*The pressure is given by $\rho gh*$)
$$eq1 = \frac{4.*10^7\,kg}{m*s^2} = = \frac{13.5\,gm*\frac{1\,kg}{1000\,gm}}{cm^3*\left(\frac{1\,m}{100\,cm}\right)^3}*\frac{9.8\,m}{s^2}*(h)$$

$$\frac{4.\times 10^7\,kg}{m\,s^2} = \frac{132\,300.\,h\,kg}{m^2\,s^2}$$
Solve[eq1, h]

 $\{ \{ h \rightarrow 302.343 \, m \} \}$

Therefore the height of the manometer was more than 302 m or 992 ft. That is more than 3 football fields in length!

A gas is confined in a 1.25-ft-diameter cylinder by a piston, on which rests a weight. The mass of the piston and weight together is $250 \, \text{lb}_m$. The local acceleration of gravity is $32.169 \, \frac{\text{ft}}{\text{c}^2}$, and the atmospheric pressure is 30.12 inches of Hg (in_Hg).

- (a) What is the force in lb_f exerted on the gas by the atmosphere, the piston, and the weight, assuming no friction between the piston and the cylinder?
- (b) What is the pressure of the gas in psia?
- (c) If the gas in the cylinder is heated, it expands, pushing the piston and weight upward. If the piston and weight are raised 1.7 ft, what is the work done by the gas in $ft * lb_f$? What is the change in potential energy of the piston and the weight?

Solution:

Part (a)

Calculate the force due to the piston and the weight:

250 lb_m * (32.169 ft / s²) *
$$\frac{1 \text{ lb}_f}{\frac{32.174 \text{ ft} * \text{lb}_m}{\text{s}^2}}$$

249.961 lb_f

240.001 10+

Calculate the atmospheric pressure in psia using the conversion factors from Appendix A. Additional conversion factor: 1 Torr = 1 mmHg.

30.12 in_Hg *
$$\frac{100 \text{ cm}_{\text{Hg}}}{39.3701 \text{ in}_{\text{Hg}}}$$
 * $\frac{10 \text{ mm}_{\text{Hg}}}{1 \text{ cm}_{\text{Hg}}}$ * $\frac{1 \text{ torr}}{1 \text{ mm}_{\text{Hg}}}$ * $\frac{14.5038 \text{ psia}}{750.061 \text{ torr}}$ 14.7936 psia

Calculate the piston area:

area =
$$\pi * \left(1.25 \text{ ft} * \frac{12 \text{ in}}{\text{ft}}\right)^2 / 4$$

176.715 in²

Now calculate the force due to atmospheric pressure:

$$\frac{\textbf{14.7936 lb}_{f}}{\textbf{1 in}^{2}} * \text{area}$$
 2614.24 lb_f

Now calculate the total force due to weight, piston, air atmosphere:

The total force is 2864.2 lbf //ANS

Part (b)

The pressure of the gas in psia is the force divided by the piston area:

$$\frac{2864.2\,lb_f}{176.715\,in^2} \\ \frac{16.208\,lb_f}{in^2}$$

The pressure of the gas is 16.208 psia //ANS

Part (c)

The system is defined as the gas in the cylinder. The system (gas) performs work by lifting the piston/weight and by expanding against the constant-pressure of the atmosphere. By equation 1.3 expansion work is given by $-\Delta(PV)$ which is $-P\Delta V$ in this case because the surrounding pressure is constant. The total pressure pushing on the gas was calculated in part (b) which accounts for the atmosphere and the piston/weight. The volume change is given by the displacement multiplied by the area.

$$\frac{-16.2081 \text{ lb}_f}{\text{in}^2} * 176.7 \text{ in}^2 * 1.7 \text{ ft}$$
 $-4868.75 \text{ ft} \text{ lb}_f$

Therefore, the system did -4869.16 ft*lbf of work on the surroundings. //ANS Work is negative since the total force and displacement are opposite in direction.

Change in potential energy is given by m*g*h:

250
$$lb_m * 32.169 \frac{ft}{s^2} * 1.7 ft * \frac{11b_f}{\frac{32.174 ft * 1b_m}{s^2}}$$
424.934 ft lb_f

The change in potential energy is 424.934 ft*lbf. //ANS

Verify that the SI unit of kinetic and potential energy is the joule.

Solution:

This problem deals with converting energy units. Students must know how to convert kinetic and potential energy from base units into Joules.

(*for kinetic energy start with
$$\frac{1}{2}mv^2*)$$

$$kg * \left(\frac{m}{s}\right)^2 * \frac{1N}{\frac{1kg*m}{s^2}} * \frac{1J}{1N*m}$$

J

(*for potential energy start with m*g*h*)

$$kg * \frac{m}{s^2} * m * \frac{1N}{\frac{1 kg * m}{s^2}} * \frac{1J}{1N * m}$$

J

The turbines in a hydroelectric plant are fed by water falling from a 50-m height. Assuming 91% efficiency for conversion of potential to electrical energy, and 8% loss of the resulting power in transmission, what is the mass flow rate of water required to power a 200-watt light bulb?

Solution:

Students must know how to convert potential energy into energy flow rate. The following conversion factors are important:

$$\frac{kg*m}{s^2}(*N*) \frac{kg*m^2}{s^2}(*Nm \text{ or joule*}) \frac{kg*m^2}{s^3}(*Nm/s \text{ or Watt*}) \frac{kg}{m*s^2}(*N/m^2 \text{ or pascal*})$$

$$\frac{kg*m}{s^3}(*Nm/s \text{ or Watt*}) \frac{kg}{m*s^2}(*N/m^2 \text{ or pascal*})$$

$$\frac{kg*m^2}{s^3}(*Nm/s \text{ or Watt*}) \frac{kg}{m*s^2}(*Nm/s \text{ or Watt*})$$

$$\frac{kg*m^2}{m*s^2}(*Nm/s \text{ or Watt*})$$

m³ s² (*This is pressure head, not power power, but they are interconvertible*)
$$\frac{490\,000\,\text{kg}}{\text{m}\,\text{s}^2}$$

By comparison to the units for Watts, these two terms differ by multiplication of ρ gh by volumetric flow in $\frac{m^3}{s}$. To illustrate, divide them:

Now add the efficiencies, noting that any losses must increase the flow rate to account for the lost energy. We do this by dividing by the efficiencies.

$$\frac{\text{LightBulbPower}}{\text{0.91*} (1 - .08) * \text{HydrostaticPressure}} \\ \frac{0.000487534 \text{ m}^3}{\text{s}} \\ \frac{\text{0.000487534 m}^3}{\text{s}} * \frac{1000 \text{ kg}}{\text{m}^3} \\ \frac{0.487534 \text{ kg}}{\text{s}} \\ \frac{\text{s}}{\text{s}}$$

The mass flow rate required is 0.4875 $\frac{kg}{s}$ or 1,755 $\frac{kg}{h}$.

Energy costs vary greatly with energy source: coal @ \$35.00/ton, gasoline @ a pump price of \$2.75/gallon, and electricity @ \$0.1000/kWhr. Conventional practice is to put these on a common basis by expressing them in \$/GJ. For this purpose, assume gross heating values of 29 MJ/kg for coal and 37 GJ/ m^3 for gasoline.

- (a) Rank order the three energy sources with respect to energy cost in \$/GJ.
- (b) Explain the large disparity in the numerical results of Part (a). Discuss the advantages and disadvantages of the three energy sources.

Solution:

Part a.

Coal < Gasoline < Electrcitiy. Ans.

Part b.

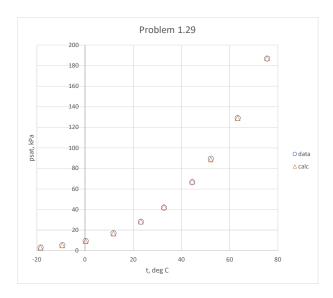

Gasoline and electricity are more expensive because they are more highly refined forms of energy requiring more infrastructure. Converting coal to electricity requires a power plant plus a train line plus and electrical power grid. Burning coal directly to produce heat energy requires only a fire box. To convert coal to mechanical energy requires a fire box and a heat engine such as a steam engine. Steam engines are mechanically very simple. Ans.
