Problem 12-1

Estimate the size of the motor necessary to pump a lean oil to the top of an absorption tower operating at a pressure of 445 kPa. The oil is to be pumped from an open tank with a liquid level 3 m above the floor through 46 m of pipe with an inside diameter of 0.078 m. There are five 90° elbows in the line, and the top of the tower is 9.1 m above the floor level. A flow of 2.7 kg/s of lean oil is required. The viscosity of the oil is 15 cP, and its density is 857 kg/m³. Assume that the efficiency of the pumping system including the motor is 40%.

Solution:

Start by making a sketch of the system such as the one shown below, and then apply the mechanical energy balance.

Assuming that the fluid is incompressible, Equation 12-12 on page 492 is the most convenient and appropriate form of the mechanical energy balance:

$$W_o = g\Delta z + \Delta \left(\frac{V^2}{2\alpha}\right) + \Delta \left(pv\right) + \Sigma F = g\left(z_2 - z_1\right) + \frac{V_2}{2} + \frac{p_2 - p_1}{\rho} + \Sigma F$$

The correction factor α is assumed to be 1 (assuming turbulent flow). Also assume that the velocity of the fluid entering the pipeline is zero, so that $V_1=0$, and that the velocity in the tower is zero, so that $V_3=0$. The velocity of the fluid inside the pipe is given by

$$V_{2} = \frac{\left(2.7 \frac{kg}{s}\right) / \left(857 \frac{kg}{m^{3}}\right)}{\pi \left(0.078 m\right)^{2} / 4} = 0.659 \frac{m}{s}$$

The Reynolds number is needed to calculate the frictional losses, and is given by

$$Rn = \frac{DV_2\rho}{\mu} = \frac{0.078m \cdot 0.659 \frac{m}{s} \cdot 857 \frac{kg}{m^3}}{0.015 \frac{kg}{m \cdot s}} = 2938.25$$

Use this value of Reynolds number to read the friction factor from Figure 12-1 on page 487, getting f=0.011.

To calculate the frictional losses, we must use Equation 12-7 on page 488. However, we must first determine the *total equivalent length* to account for the elbow, using Table 12-1:

$$L = 46m + 5 \cdot 32 \cdot 0.078m = 58.48m$$

$$F = \frac{2 \cdot f \cdot V^2 \cdot L}{D} = \frac{2 \cdot 0.011 \cdot \left(0.659 \frac{m}{s}\right)^2 \cdot 58.48m}{0.078m} = 7.163 \frac{m^2}{s^2}$$

There are also frictional losses F_C due to the sudden constriction where the fluid enters the pipe. F_C for sudden constriction is given by the equation in Table 12-1 on page 490:

$$F_{\rm C} = \frac{K_{\rm C} \cdot V^2}{2 \cdot \alpha} = \frac{0.4 \cdot 1.25 \cdot \left(0.659 \, \frac{\rm m}{\rm s}\right)^2}{2} = 0.109 \, \frac{\rm m^2}{\rm s^2}$$

Note that K_C is really a function of the big and small areas of the constriction (A_1 and A_2 in the sketch), but the maximum value is $0.4 \cdot 1.25$.

There are also frictional losses F_E due at the end of the pipe due to the sudden expansion where the fluid enters the column. F_E for sudden expansion is given in Table 12-1 on page 490:

$$F_{e} = \frac{\left(V_{2} - V_{3}\right)^{2}}{2 \cdot \alpha} = \frac{\left(\sim 0 - 0.659 \, \frac{m}{s}\right)^{2}}{2} = 0.217 \, \frac{m^{2}}{s^{2}}$$

Now, go back and apply the mechanical energy balance:

$$W_o = 9.8 \frac{m}{s^2} \cdot \left(9.1 m - 3.0 m\right) + \frac{445000 Pa - 101325 Pa}{857 \frac{kg}{m^3}} + \frac{\left(0.659 \frac{m}{s}\right)^2}{2} + \left(0.109 + 7.170 + 0.217\right) \frac{m^2}{s^2} = 468.5 \frac{m^2}{s^2} + \frac{10.109 + 10.000 Pa}{s^2} + \frac{10.1000 Pa}{s^2} + \frac{10$$

To convert this answer to Watts, multiply by the mass flow rate:

$$W_o = 468.5 \frac{m^2}{s^2} \cdot 2.7 \frac{kg}{s} = 1265.0 \text{ Watts}$$

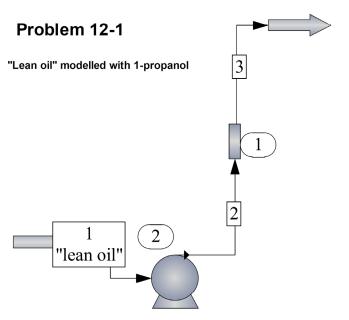

To calculate the power input to the pump-motor system, divide by the efficiency:

$$W_{in} = \frac{1265.0 \text{ Watts}}{0.4} = \frac{3162.5 \text{ Watts}}{4 \text{ NS}}$$

This problem would be fairly easy to solve in ChemCAD if the chemical composition of the lean oil were known. However, this was not given. The key to the problem is therefore to identify a reasonable component that matches the density and viscosity of the lean oil. This is sometimes referred to as using a "psuedo-component."

After some searching, I settled on 1-propanol at 231.5 K, which is a pretty close match. The given density was 857 kg/m3 and the viscosity was given as 15 cP. The corresponding values for 1-propanol at 231.5 K are 854.4 and 14.98.

The calculated pump power of 3168 J/s is in good agreement with the value of 3163 W from the by-hand calculations. The small difference is due to small differences in viscosity and density and the Le/D values used by CHEMCAD.

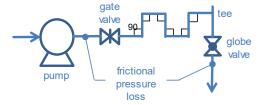

The pipeline tool allows the user to set fluid properties to their own values and then override the CHEMCAD values. Trying this and changing the density and viscosity to the values given in the problem statement, changes the Reynolds number from 3009 to 2938, in excellent agreement with the by-hand calculations. However, this changes the pump power from 3168 W to 3170, or an increase of 2 W. So there is an effect, but it is small and in the wrong direction.

Problem 12-2

What is the pressure loss when 2.14 kg/s of pure benzene at 40 °C flows through a 21-m length of straight pipe with an inside diameter of 0.0409 m? The pipeline contains six 90° elbows, one tee used as an elbow (equivalent resistance equal to 60 pipe diameters), one globe valve, and one gate valve. The density of benzene is 849 kg/m³, and its viscosity at 40 °C is 5×10^{-4} Pa·s.

Solution:

Start by making a sketch of the system, and then apply the frictional loss Equation 12-7, p. 488.

Start with velocity inside the pipe, which is given by

$$V_{2} = \frac{\left(2.14 \frac{kg}{s}\right) / \left(849 \frac{kg}{m^{3}}\right)}{\pi \left(0.0409 m\right)^{2} / 4} = 1.919 \frac{m}{s}$$

The Reynolds number is given by

$$Rn = \frac{DV\rho}{\mu} = \frac{0.0409 \, \text{m} \cdot 1.919 \, \frac{\text{m}}{\text{s}} \cdot 849 \, \frac{\text{kg}}{\text{m}^3}}{0.0005 \, \frac{\text{kg}}{\text{m}^6}} = 133,271$$

Use the Reynolds number, read the friction factor from Figure 12-1 on page 487, getting f=0.0055. The total equivalent length accounts for the elbows, tee, and valves (Table 12-1):

$$L = 21m + (6.32 + 60 + 300 + 7) \cdot 0.0409m = 43.86m$$

$$F = \frac{2 \cdot f \cdot V^2 \cdot L}{D} = \frac{2 \cdot 0.0055 \cdot \left(1.919 \frac{m}{s}\right)^2 \cdot 43.86m}{0.0409m} = 43.440 \frac{m^2}{s^2}$$

To convert this answer to Pa, multiply by the density:

CHEMCAD answer is 37.1 kPa (set roughness correctly!)

ANS may vary slightly depending on how you read the "Moody Plot"

$$F = 43.440 \frac{m^2}{s^2} \cdot 849 \frac{kg}{m^3} = \frac{36,881 \text{ Pa}}{\text{ANS}}$$
(set roughness correctly!)

Excel answer is 43.5 N·m/kg
36.9 kPa when multiplied by ρ

36.9 kPa when multiplied by ρ (essentially the same)

	Velocity on wide side of constriction/expansion	V _{wide}	m/s	0.00192	not named	s/c, volumetric flow divided by area of wide side
	Losses due to enlargements	Fe	m ² /s ² or N·m/kg	1.83727	not named	s/c, Table 12-1, p. 490, sudden enlargement
	Losses due to constrictions	F _c	m ² /s ² or N·m/kg	0.91974	not named	s/c, Table 12-1, p. 490, sudden constriction
	Number of enlargements		dimensionless	0	not named	u/s, typical value is 1 for pipe emptying into a vessel
	Number of constrictions		dimensionless	0	not named	u/s, typical value is 1 for pipe removing liquid from a vessel
	Losses due to enlargements and constrictions	F _e +F _o	m ² /s ² or N·m/kg	0.00000	not named	s/c

CHEMCAD Solution

CHEMCAD gives a pressure drop of 37,077 Pa, compared to 36,881 Pa from the by-hand calculation. CHEMCAD allows input of the exact same properties, so the difference is not due to the property estimations in CHEMCAD. There is a difference in friction factor. CHEMCAD uses 0.0222 and in Lesson 2, I showed 0.022, which accounts for the difference.
